## **Abstract**

Web-based Alternative for Teachers Assistants to Submit Time Sheets.

GAMBILL, JOSHUA (Department of Mathematics and Computer Science), MYERS, DR. BARRY (Department of Mathematics and Computer Science).

A web-based application that provides teachers assistants with an online alternative to submitting timesheets. This application gives teachers assistants the ability to enter, save, and upload hours worked through a server hosted on the Computer Science Department servers. Teachers are given the ability to view registered students and their respective hours. System Admins are given the ability to see the registered students, their time sheets, registered teachers, and their students. The front end of this application was developed using Sublime Text with HTML, CSS, and JavaScript to display the user interface for different levels of user as well as a login page. The database was developed using MySQL hosted on a XAMPP server to store time sheets, registered users, and passwords. The server uses phpMyAdmin as an administration tool to manage all information uploaded to the server. The front end website was connected using PHP scripts written with the functionality to give users different information upload options based off of user type. The server is scheduled to be implemented on the Computer Science Department servers but is currently implemented on a desktop personal computer.

## **Overview**

The goal of this project is to offer a web-based alternative to Teachers Assistant timesheet system that is currently in use. This includes both front-end development of a web application and back-end development of a MySQL database to store any information necessary. Specific desired functionalities include the ability to register as a student, professor or admin, at the level of student the ability to upload start and stop times, dates, and total work hours to the database. At the professor access level, the ability to observe current active students currently registered to that specific professor, accept or deny registered students, and save reports based off of specific students. For the admin access level, the ability to observe both active students and professors, accept or deny registering professors and students, upload additional information about specific students, and save reports based off of particular professors or students.

## **Background**

In the various departments that together make up the Science Departments at Northwest Nazarene University (NNU), it is common for individuals to have several Teachers Assistants (TAs). These TAs are hired to complete tasks such as grading, running labs, and research. To keep track of student hours worked there is a system that has been implemented. The system is based on the use of Google Sheets.

The structure of this systems has three separate types of users; students, professors, and an admin. Each student is assigned a Google Sheet that has space to input information such as time in, time out, hours worked, and tasks. Each sheet is also shared with the specific professor that each student is doing work for, the professor has the job of approving monthly totals for each student. The admin has the responsibility of making sure that all students have submitted

hours and all professors have approved of these hours along with running a master spreadsheet that contains other information such as budget numbers.

This project aims to replace this system with a web-based application that not only automates most of the processes but also helps maintain data integrity. This application seeks to limit human error that comes from manual number transfers from student time sheets to the master spreadsheet. Another feature is to improve data extraction, a professor or an admin will be able save CSV files based off of specific parameter as opposed to manually searching for that information in several Google Sheets.

## **Analysis and Design**

The initial design of this application began by merely observing the structure of the current spreadsheet system. This was done by noting what information each level of the user could view and what information each user inputs into their respected spreadsheets. The student user level readily has access to the least amount of information as these users do not need to know who else is working as a TA and their hours. The Professor user, on the other hand, had access to all of the student hours under their employment and through the Student Activities form that the student turns in to fully become employed, they have power over who can become a TA.

At Admin user level, each user has complete access to all information about both students and professors. An admin user also has the responsibility to add other information about each student such as budget number, total pay, Post Office Box numbers, and hourly rate. Other required functionalities include having an active TA and Professor list, control over who can become a TA despite approval by professors, and a way to actively retrieve data about a specific

student or professor. Through understanding the information that each level of user has, a design of the database and web application were able to begin.

The database of this project is the most critical component. Without it the website would only be several buttons and input bars without function. Using information gathered from system analysis, the five primary entities were identified and would be used to build the database in the design stage. The first three tables would represent the three user levels and store login information. The tables were simple name student, professor, and admin. The other two tables were based on data uploaded from different users, that being the budget table and the timesheet table. Using MySQL Workbench and the data collected from the analysis stage, the first Entity Relationship Diagrams (ERD) were created. Though several iterations were built over the course of development, the ERD shown below represents the different tables used to construct the final database.

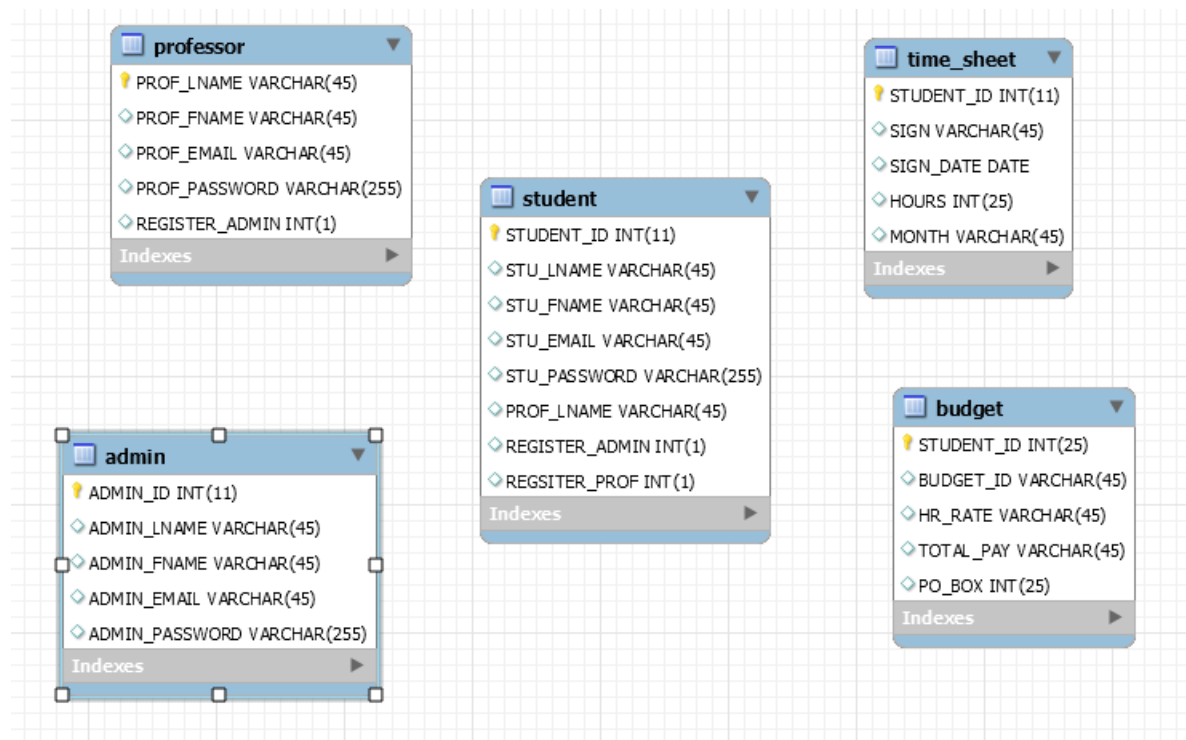

Figure 1 Tables Used to Create the Final ERD

## Web Development

The development stage of this project was split into three separate parts, the first being the development of the website interface. The first challenge was to implement different pages to be used to implement all the functional requirements of each level of a user. As well as creating an interface that allows easy navigation through all of these pages, but only the pages that each user level has access to. This was achieved through the inclusion of a navigation bar directly under the central header that contains different options based off of who is logged into the website.

The student site is the simplest due to the fact that a student level user has only the permissions to view and edit their time sheets. Through the use of several JavaScript functions, specific drop-down buttons could show a different months' time sheet based off of the user's selection. Each month has a form for the student to enter their information, one line per scheduled time, with the addition of an add button that adds another row gives the user the ability to add multiple numbers of scheduled work times along with the feature to delete any unused rows. This again was accomplished using JavaScript functions.

```

/*****
 * These javascript functions are used for the dropdown menus in the student time sheets pages, each dropdown gives the
 * student the option of selecting different semesters and different months, on select each shows a certain page based
 * off of the student's selection.
 *****/

function sem() {
    document.getElementById("semDropdown").classList.toggle("show");
    window.onclick = function(event)
    {
        if (!event.target.matches('.semDropBtn'))
        {
            var dropdown = document.getElementsByClassName("semContent");
            var i;
            for (i = 0; i < dropdown.length; i++)
            {
                var openDropdown = dropdown[i];
                if (openDropdown.classList.contains('show'))
                {
                    openDropdown.classList.remove('show');
                }
            }
        }
    }
}

```

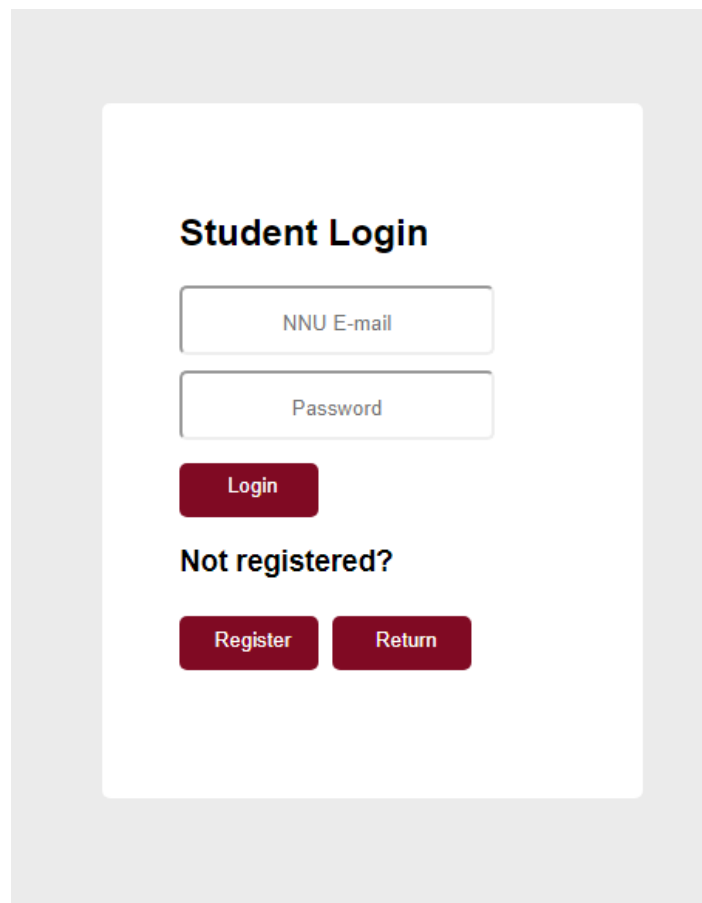

Figure 2 JavaScript Function With that Creates the Student Semester Dropdown Menu

Figure 2 is an example of one of these JavaScript functions. This function specifically, named `sem()` is used to create a drop-down menu of which the student selects the semester they are working in. The three options; Spring, Fall, and Summer then present the user with a separate drop-down menu that allows them to select the month for which they wish to submit hours for. However, due to the student selecting the semester, the month dropdown will only give the user the option to select months that are a part of that semester. Figure 3 shows a JavaScript function that was implemented to add up total hours for each month; the total was displayed in a separate form that contains an input for a date, a signature, and student id number. These functions slightly altered and reused for pages in both the Admin and Professor sections of the website, precisely the layout of the page was kept constant across all users along with any drop-down menus. Because all of the functionality of the Admin and Professor pages rely on back-end PHP scripts to fulfill the functionality requirements, therefore, it will be discussed in full in a different section.

```
function monthSum(){
    var arr = document.getElementsByName('dayTotal');
    var dayTotal=0;
    for(var i=0;i<arr.length;i++){
        if(parseInt(arr[i].value))
            dayTotal += parseInt(arr[i].value);
    }
    document.getElementById('monthTotal').value = dayTotal;
}
```

*Figure 3 JavaScript Function That Calculates the Total Hours From a Time Sheet*

The next section of the web development stage was to create the login pages. However, since there are three levels of users, the website required three login pages for the different types of users. A separate page was developed that contained buttons that linked to each of these login pages, these buttons allow a user to select what page they wish to view. Each button when clicked navigated to a different user level login page. The login page followed the same styling that was created for the student time sheet page. The page itself simple contained an input box for the user's email and password as shown in Figure 4.

The image shows a 'Student Login' form. At the top, the title 'Student Login' is displayed in a bold, black font. Below the title are two input fields: the first is labeled 'NNU E-mail' and the second is labeled 'Password'. Both fields have a light gray border and a subtle shadow. Below the input fields is a dark red button with the text 'Login' in white. Underneath the button is the text 'Not registered?' in a bold, black font. At the bottom of the form are two dark red buttons: 'Register' on the left and 'Return' on the right, both with white text. The entire form is centered on a light gray background.

*Figure 4 Student Login Form*

## Database Development

The second development step was to create the database that the website would have a connection with. The software that was used includes XAMPP to host an Apache and MySQL server, and it was decided that PhpMyAdmin would be used as an administration tool for development. PhpMyAdmin gives the developer the ability to manipulate different aspects of the database without having to do most of it by hand. PhpMyAdmin also has the ability to observe when and what types of data were inserted which is an essential part of developing the connection between the database and the web service.

The database itself was created using MySQL in PhpMyAdmin and utilized all the design information mentioned in the design section. In the student table, student ids were selected to be the primary key specifically because each student's id number is unique to that person. Student ID would also be helpful in some of the other tables such as the time sheet and budget tables as a foreign key. This allows all the information that has been inputted about a student to be linked directly to that student based off of that student's unique ID.

When a student registers on the website they are asked to insert the last name of the Professor that they are working for. This allows the student database table to utilize the column PROF\_LNAME as a foreign key to enable all students under a specific Professor to be linked. If each student is connected to their professor, then a query to select all students under that professor's last name is a much more straightforward task. Figure 5 shows the completed final database and the relationships between the tables

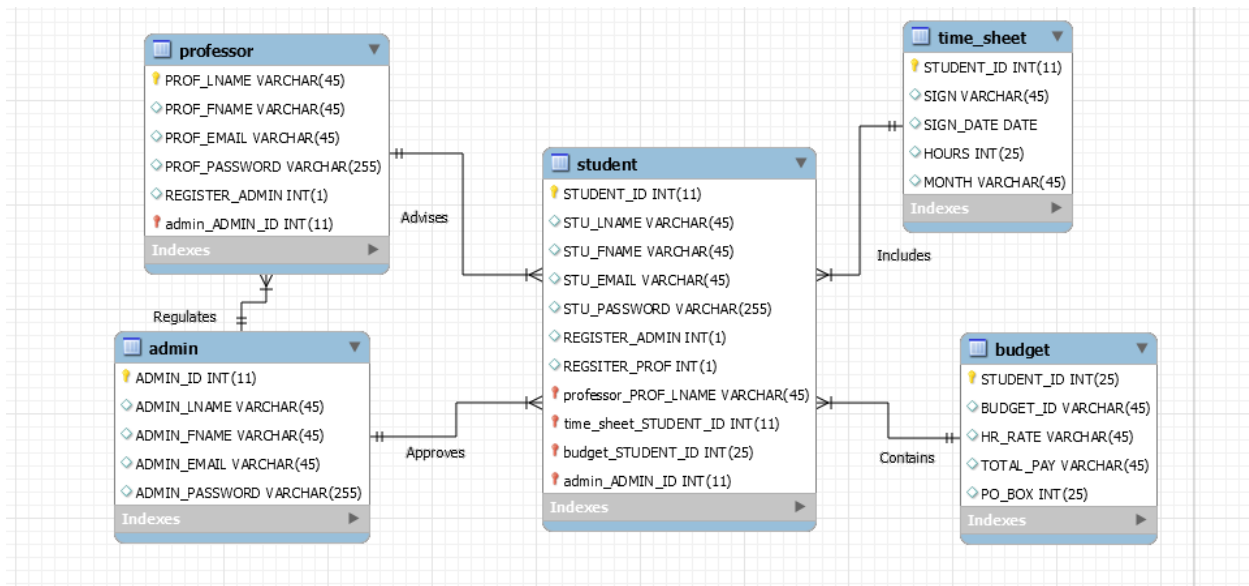

Figure 5 Final ERD Diagram

## Connection

With the two first parts completed, general layout of the website and the server hosting a database for it to connect it to the last piece of the project, the connecting between the server and the website was next. The language PHP was chosen, and the login system was the first area of connection development. Using the already created login page, a registration page was designed based off of the general layout used for all the other pages. However, there were three separate registration pages created due to the different types of information required for each level of a user.

Using PHP, a general login system was developed with certain types of error handling implemented. This system uses if/else statements to perform the error handling for different types of errors. For example, when a student registers the form asks for the student's ID, last and first name, email, password, and professor. When a student is entering this information but presses the submit button without filling out everything without any error handling the PHP

script will attempt to insert nothing into a database. This type of activity could either cause null fields or other problems. The first set of if/else statements uses the PHP function `empty()` to check whether each area has been filled as shown in figure 6.

```
/* Check for empty fields */
if (empty($id) || empty($FName) || empty($LName) || empty($email) || empty($password) || empty($profName)) {
    header("Location: ../RegisterStudent.php?RegisterStudent=empty");
    exit();
}
```

*Figure 6 If Statement that Checks for Empty Fields*

The next set of error handlers checks the content of the first and last name input boxes. If a student accidentally puts a number into one of the name input boxes, the error handler will catch this because it compares the input information against a set of acceptable values. In the case of this input box, the acceptable values range from a to z and A to Z only, since there is a number in one of the names the function throws an error. Other issues such as valid emails addresses are also checked, the function `FILTER_VALIDATE_EMAIL`, does precisely this and if, the email address is invalid an error is thrown.

One preventative function that has been implemented is the ability to check against registered users to ensure that the user that is currently registering is not already registered. This is done by a SQL query that calls all users with, in the student's case, the same Student ID. If there are any results, an error is thrown. If there are no results then the student is registered, and their information is pushed to the database.

An added security measure that is implemented after all of the error handlings is the `password_hash()` function, which as the name suggests, hashes the inputted password before pushing it to the database. The purpose for this is to help prevent passwords from being completely visible from the PhpMyAdmin page. Instead, a seemingly random string of

characters would be displayed. Figure 7 demonstrates how this function was implemented in this case. The next step is to use a simple INSERT INTO query to push the login information to the database. All three registration forms use this same system with the different syntax to fit the differences between the tables.

The screenshot shows a table with the following columns: STUDENT\_ID, STU\_LNAME, STU\_FNAME, STU\_EMAIL, and STU\_PASSWORD. Each row represents a student record. The STU\_PASSWORD column contains long, alphanumeric strings representing hashed passwords. Below the table, there are controls for selecting, editing, copying, deleting, and exporting the data.

	STUDENT_ID	STU_LNAME	STU_FNAME	STU_EMAIL	STU_PASSWORD

Figure 7 The Hashed Password Displayed In PhpMyAdmin

One of the main requirements for both the Admins and the Professors is the ability to see active students and certain information about them. Using PHP scripts, a list of students was generated based off of current information in the database by using a SELECT \* FROM student query, which returns all data from the student table. Through a while loop to obtain all the results from the query, each result was added to the list on the Admin web page displaying the specific information: Student ID, student first and last names, and emails. The professor page uses the same query but with a modification that selects all students from the student table that have the logged in professor as their professor.

### Future Work

There are some functionality requirements that were not completed for this project; the first has to deal with the registration of students and professors. To avoid students that are not cleared to be TAs each professor has to approve the registration of each student. This will be

accomplished in a similar way that the list of active students was achieved. The main difference is that there will be two buttons along with each listed pending student, an approve and deny. The final project would have PHP scripts behind each button, one validating the registered student, the other removing the student. This same process would be used for the admin for both pending students and professors.

The last area that needs to be completed is the reports tab of the website. For the functionality requirements for this project, both the Admin and the Professors require the ability to print reports on registered students with information like their total hours, budget information, associate professors, and all other information stored about each entity. The tab on the webpage is to have a form where the user can specify what information they want from the database. When they press the save button the database is queried and all the specified information is saved to an external CSV file.

## **Conclusion**

Despite some uncompleted features, most requirements were met, and with future work, this website can eventually replace the current TA timesheet system. This new alternative will help the process of students filling out a time sheet and professors approving these time sheets to happen more efficiently and reduce the number of errors by storing all the input information in a database rather than a spreadsheet.
